# Global land cover mapping

1994 - 111km

1998 - 8 km

2000 - 1 km

2002 - 0.5 km

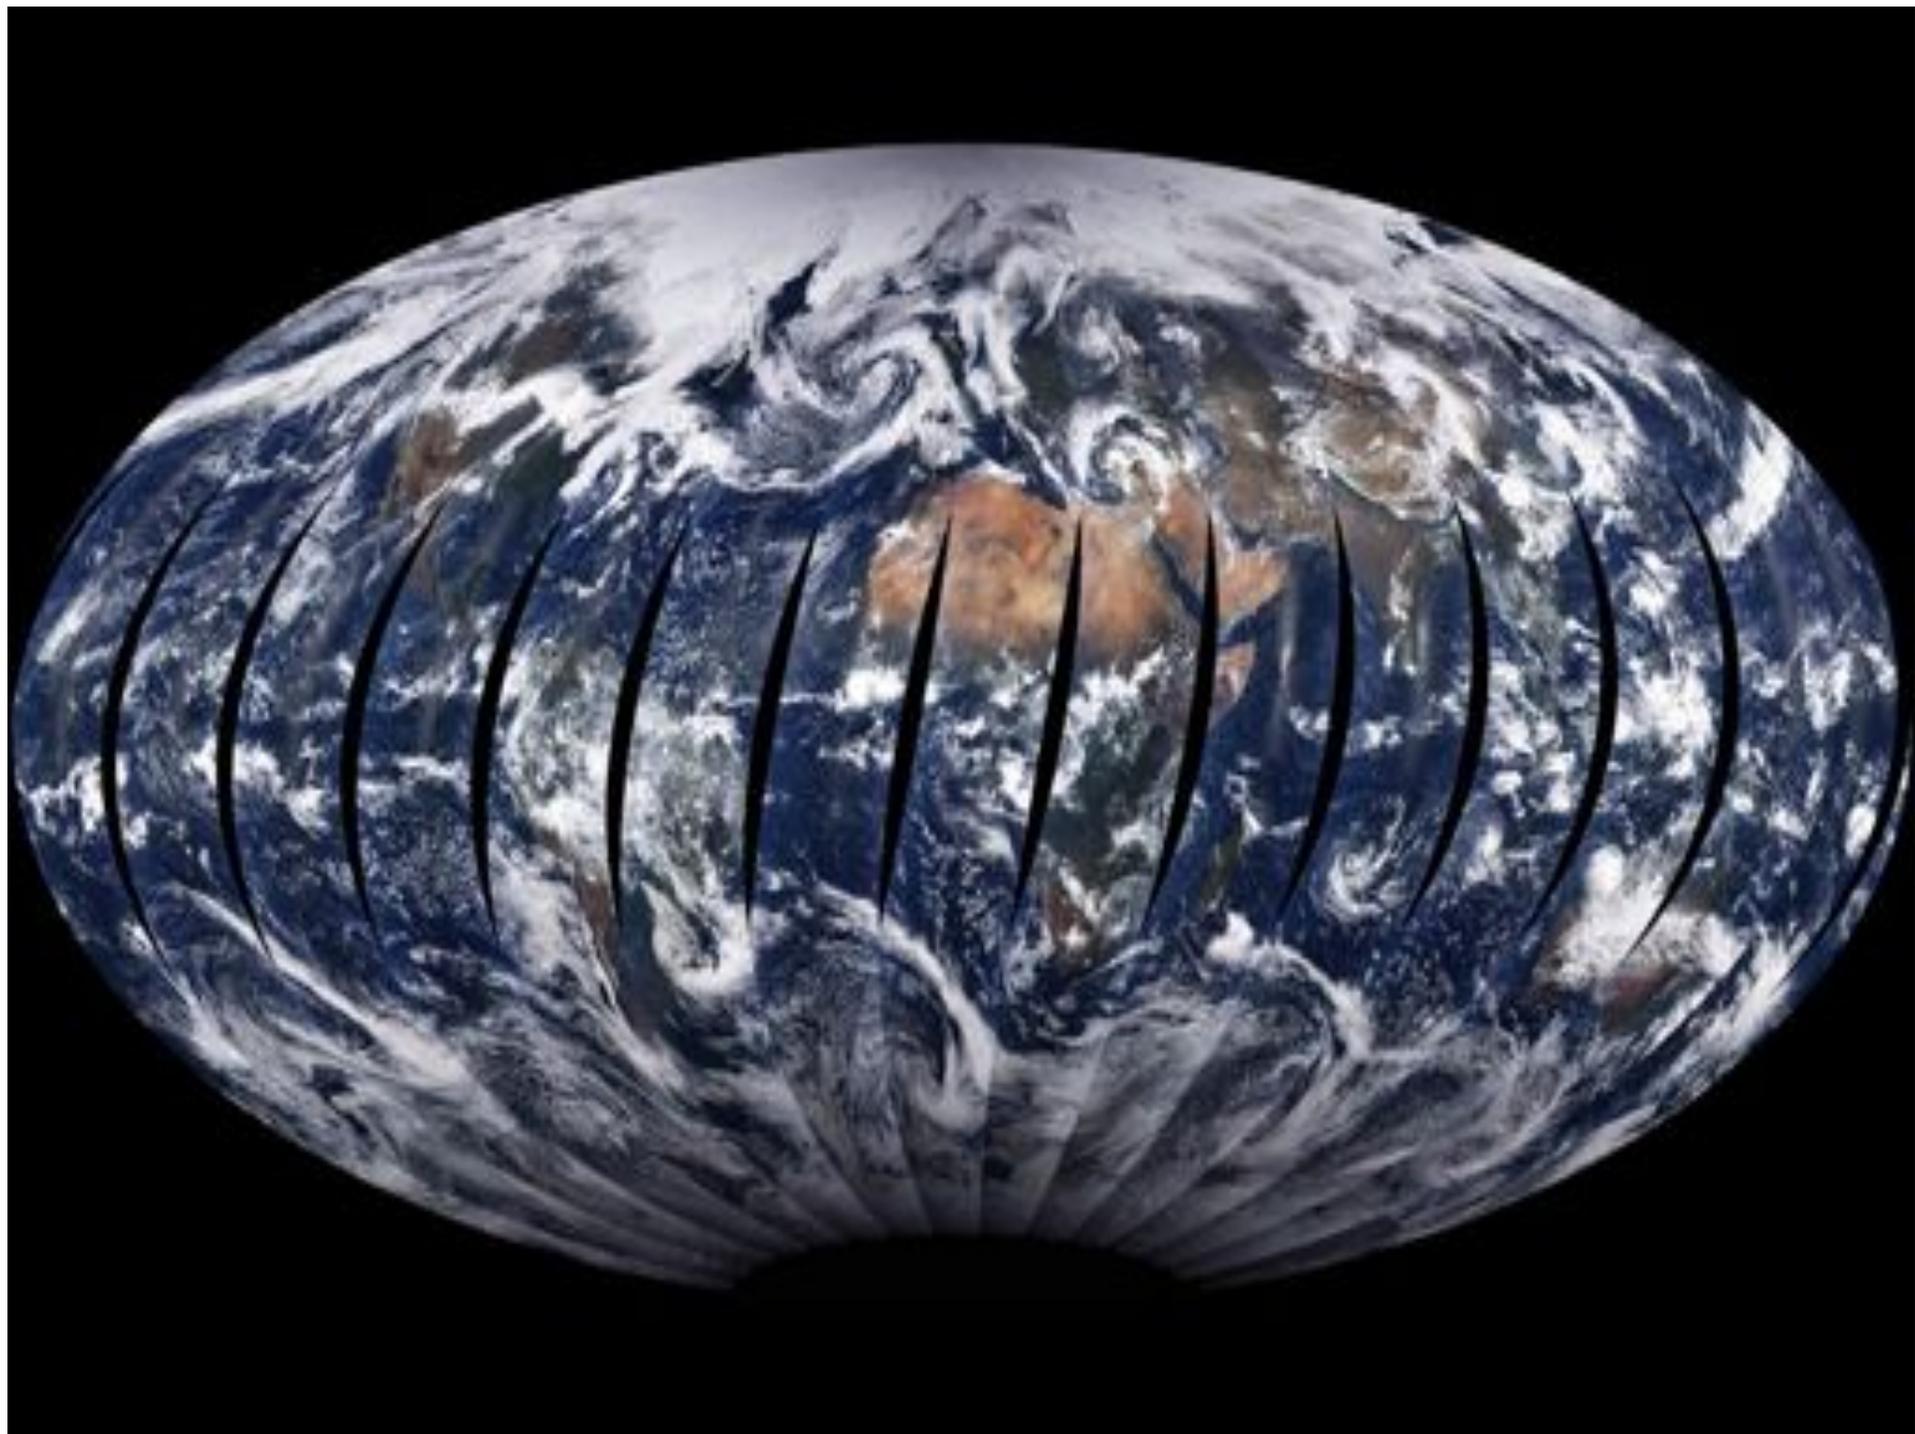

2006 - 0.25 km

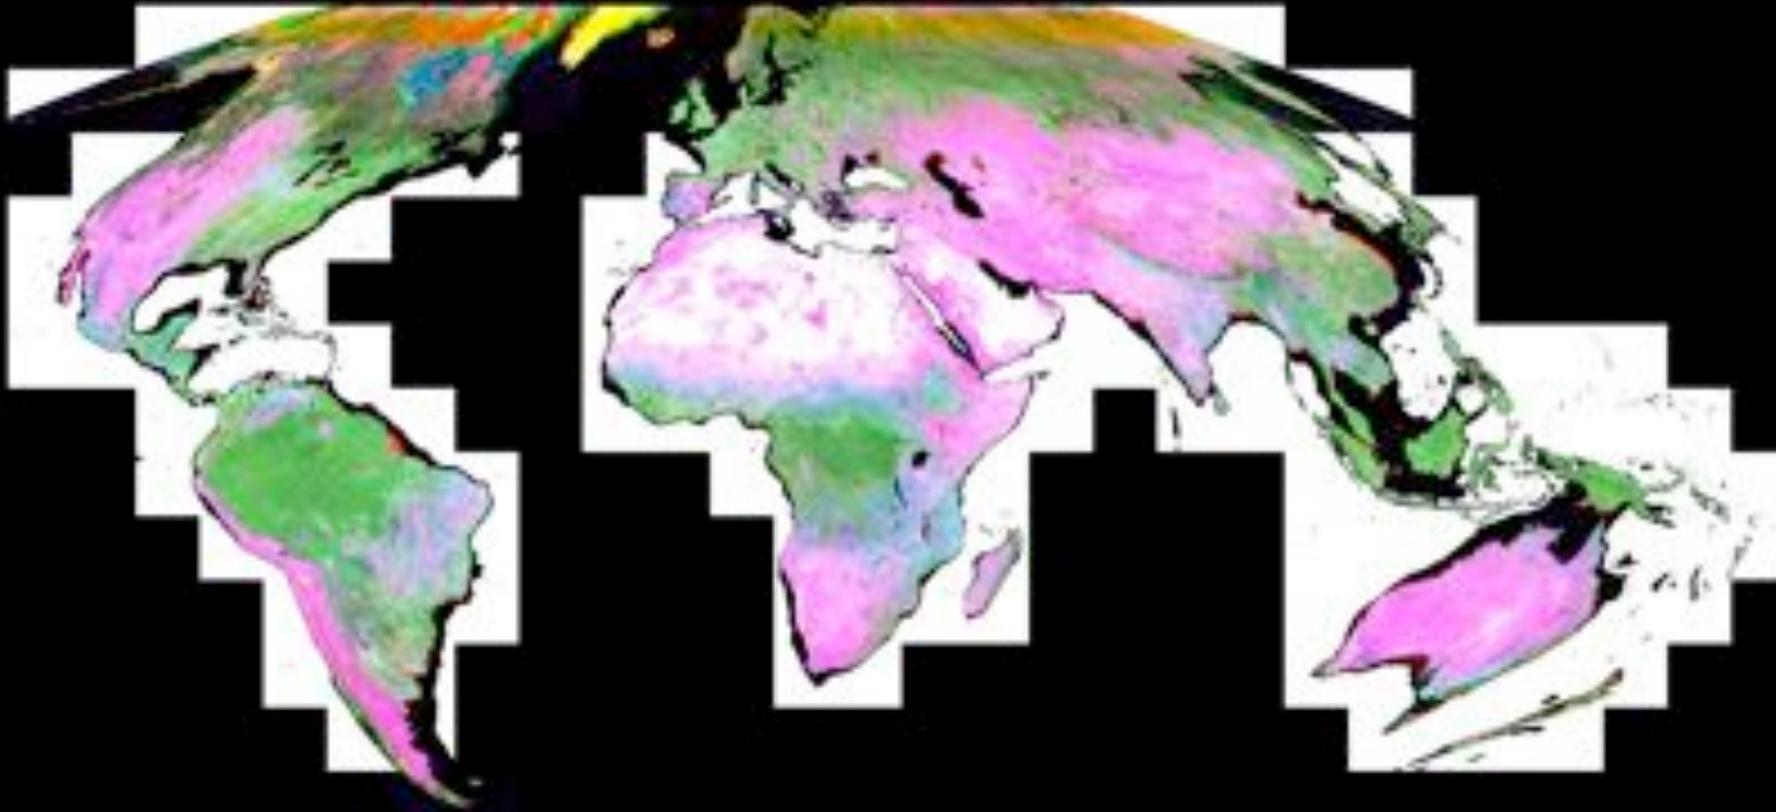

2010 - 0.03 km

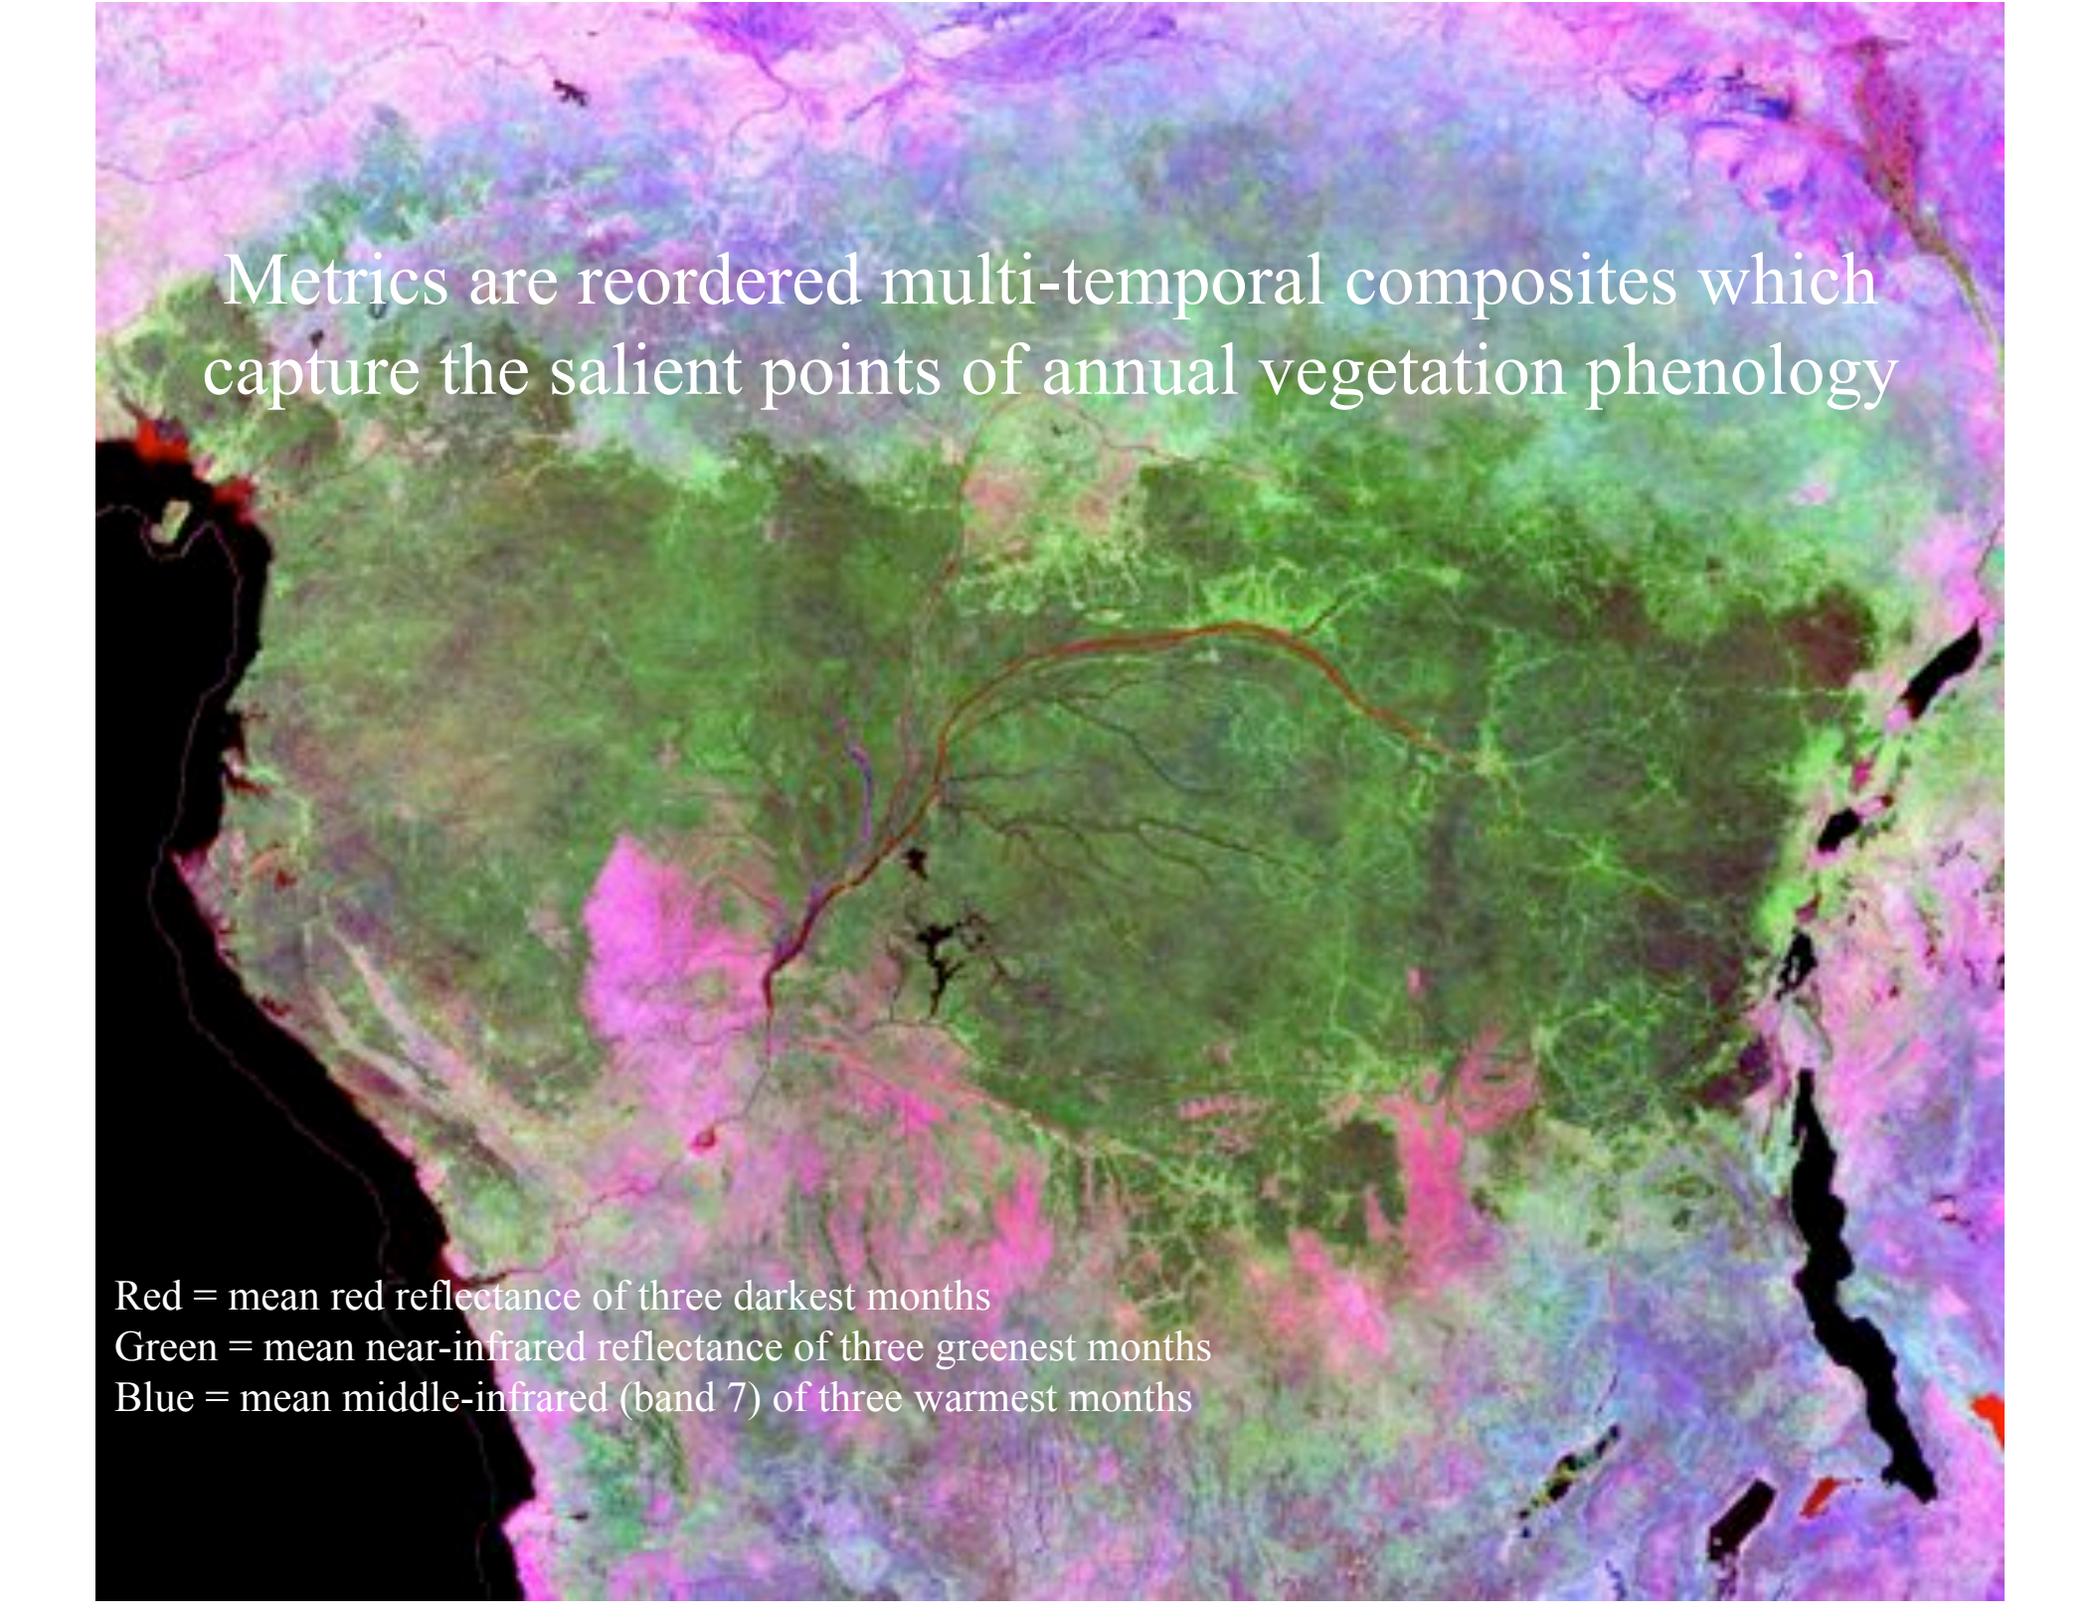

# Global MODIS metrics

Red = mean red reflectance of three darkest months

Green = mean near-infrared reflectance of three greenest months

Blue = mean middle-infrared (band 7) of three warmest months

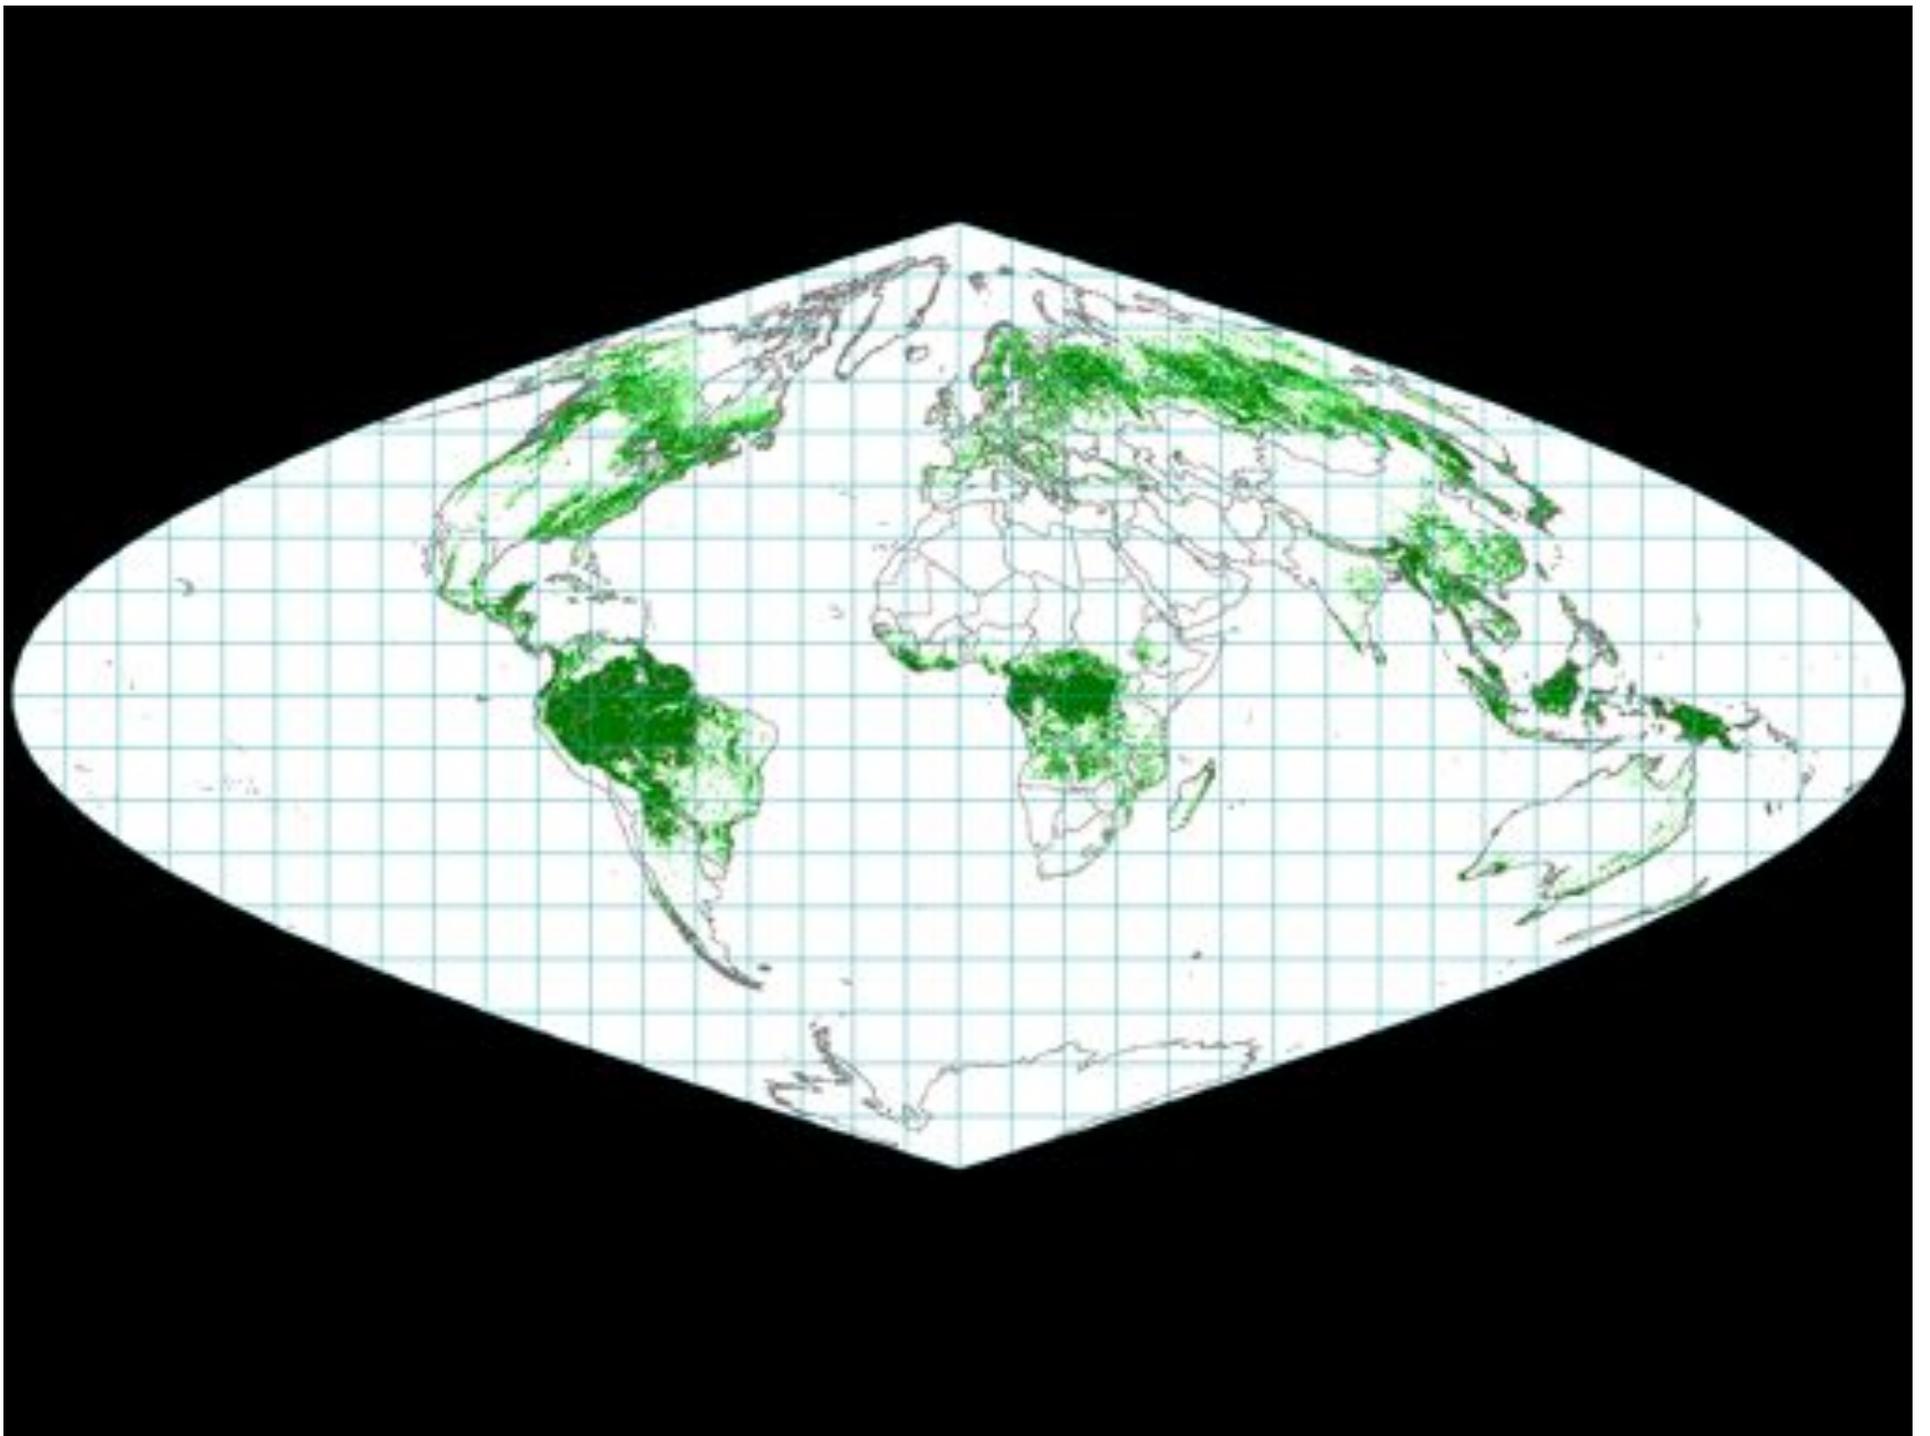

Metrics are reordered multi-temporal composites which capture the salient points of annual vegetation phenology

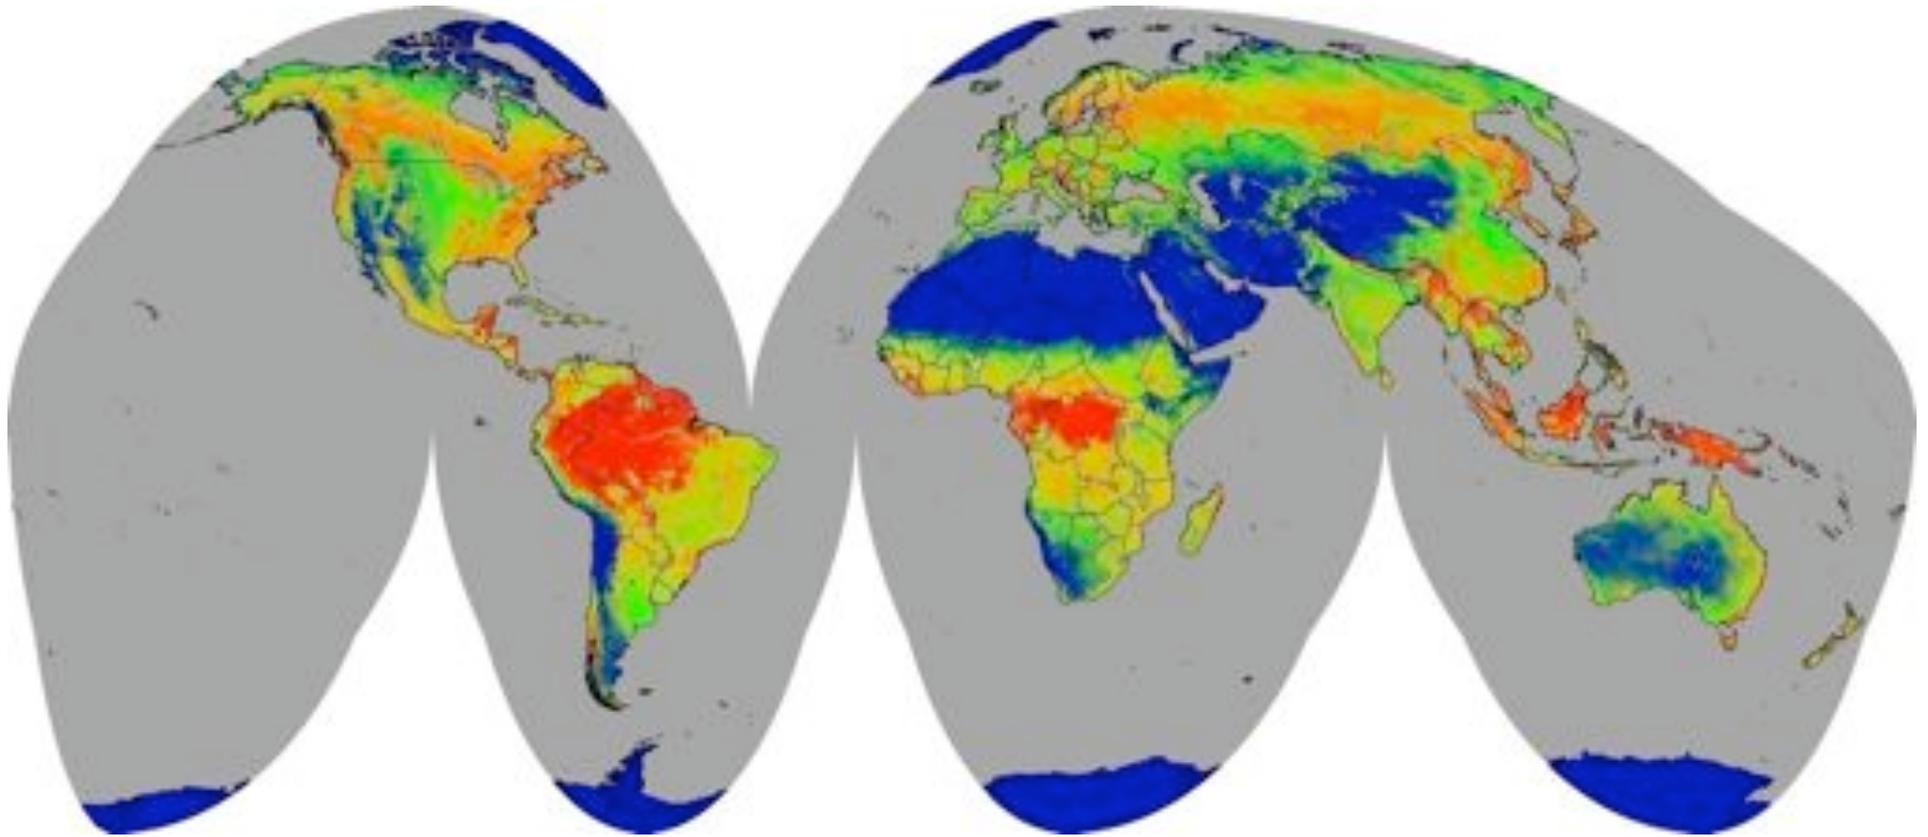

Red = mean red reflectance of three darkest months

Green = mean near-infrared reflectance of three greenest months

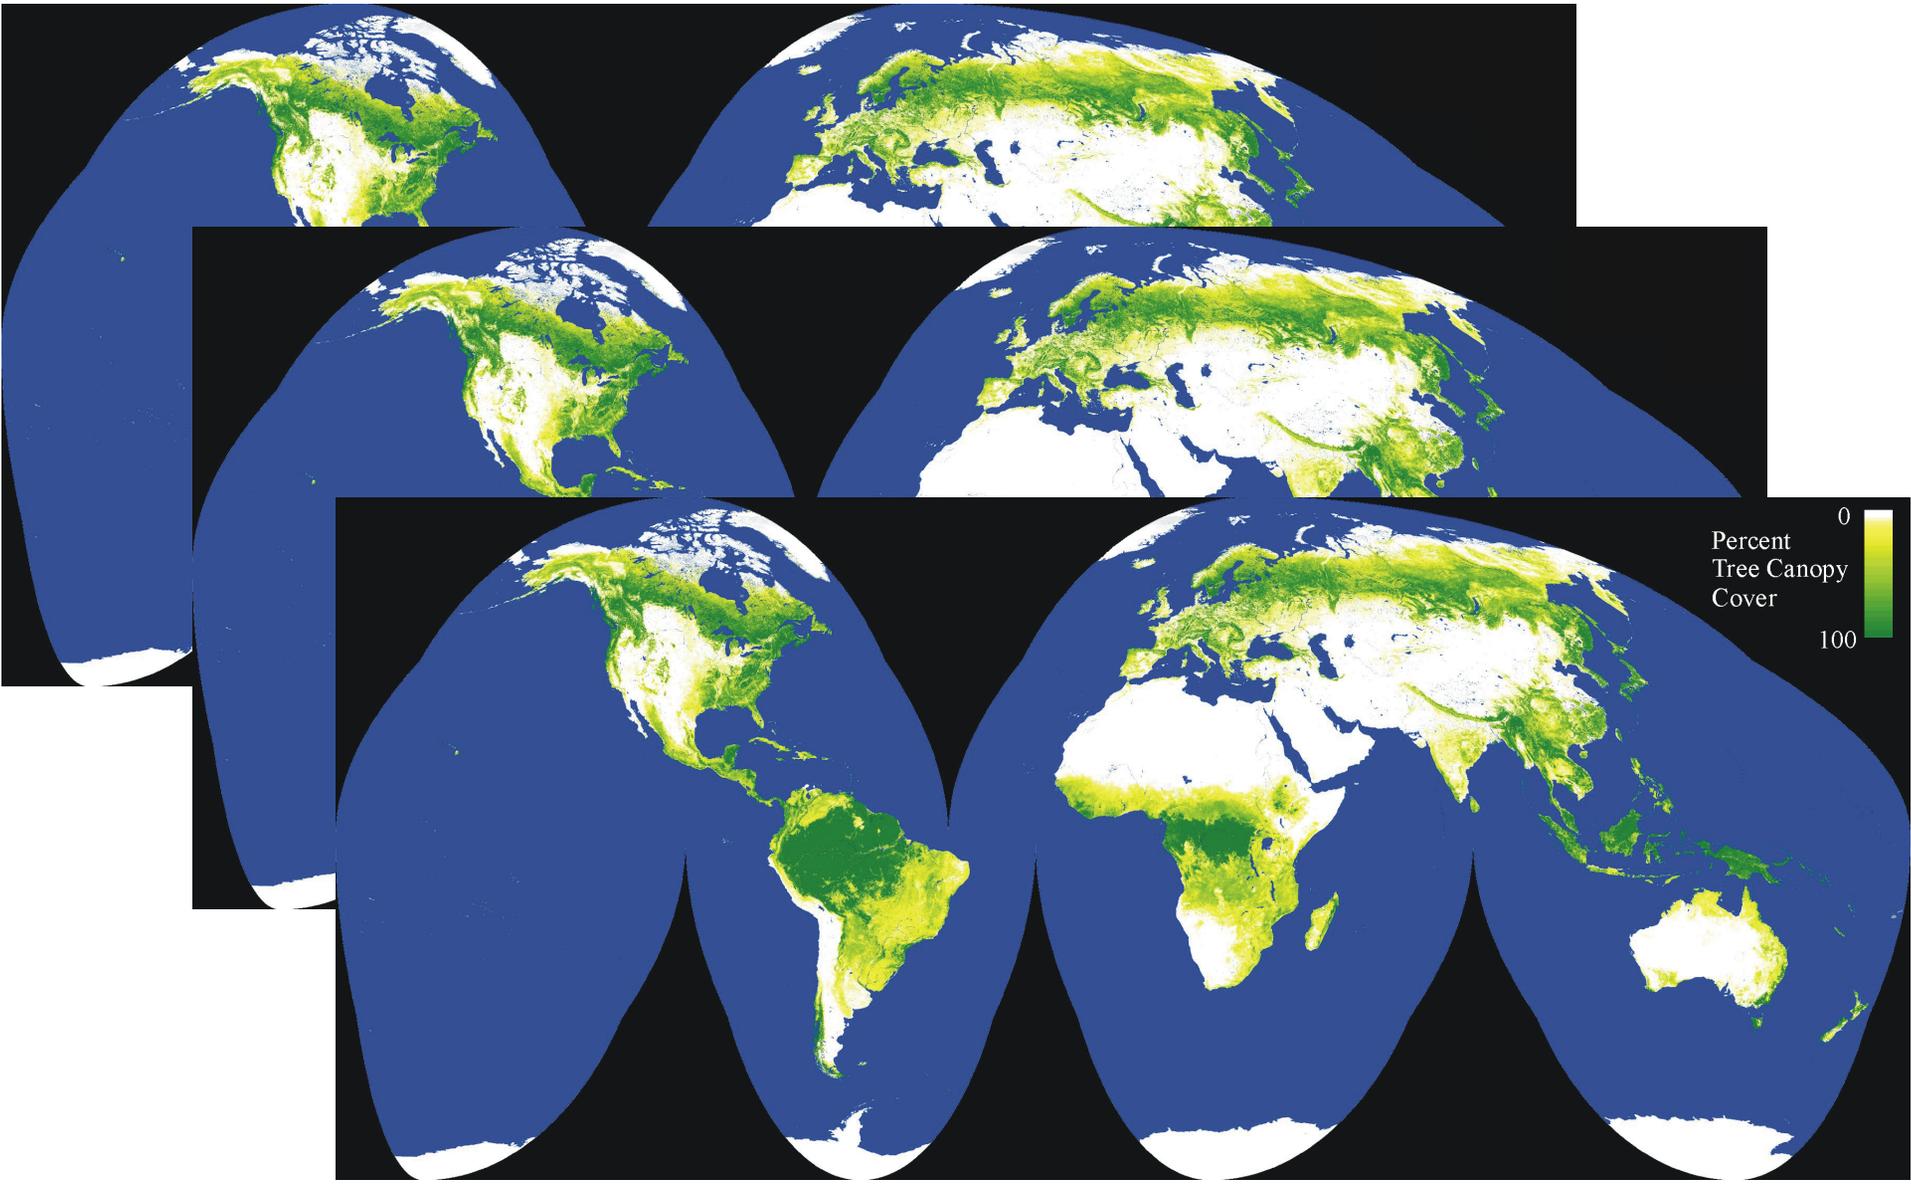

Blue = mean middle-infrared (band 7) of three warmest months

# MODIS Vegetation Continuous Fields – 2000

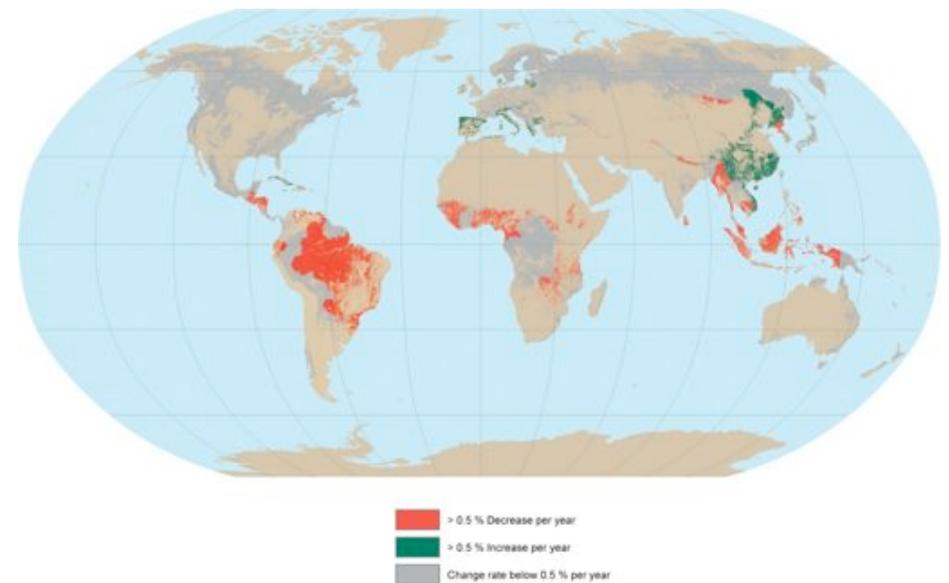

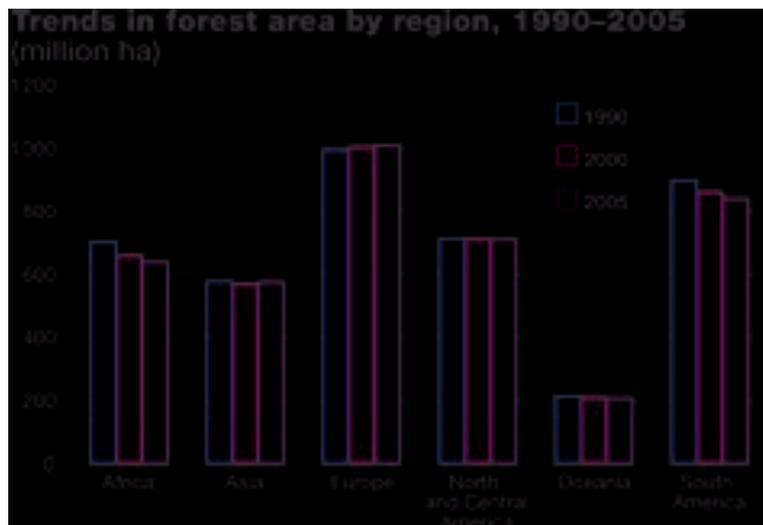

# Annual updates of land cover

# United Nations Food and Agriculture Organization Forest Resource Assessment Report

- Africa and South America feature largest forest losses
- Overall rate of forest loss continues to decrease

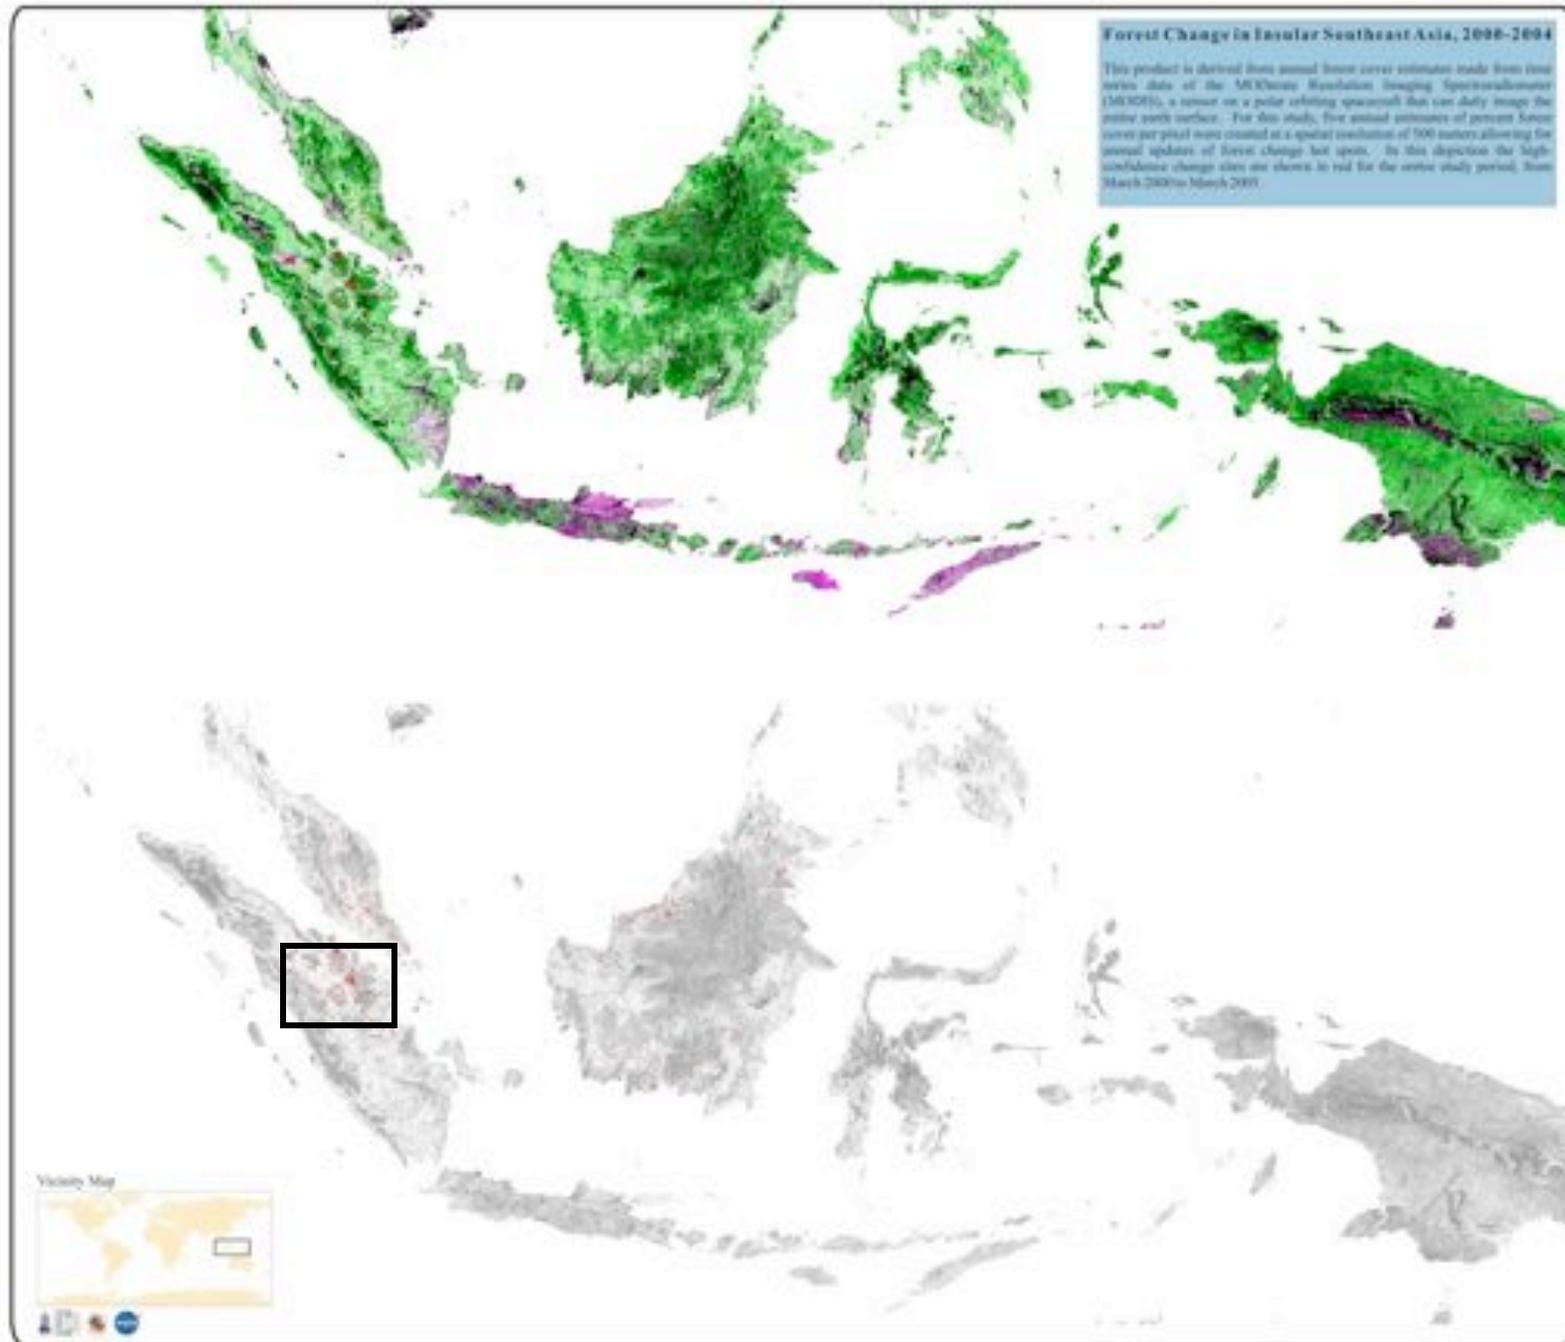

# Forest definitions

- IPCC Good Practice Guidance
  - Forest is a minimum area of land of 0.05 – 1.0 hectares with tree crown cover (or equivalent stocking level) of more than 10 – 30 percent with trees with the potential to reach a minimum height of 2 – 5 meters at maturity *in situ*
- Our current definition
  - .09 hectares (one Landsat pixel) with tree crown cover  $\geq 30$  percent for trees  $\geq 5$  meters in height
  - Optical data cannot reliably quantify sparse and/or short tree cover in the context of monitoring

# Forest monitoring using MODIS and Landsat data sets – first approach

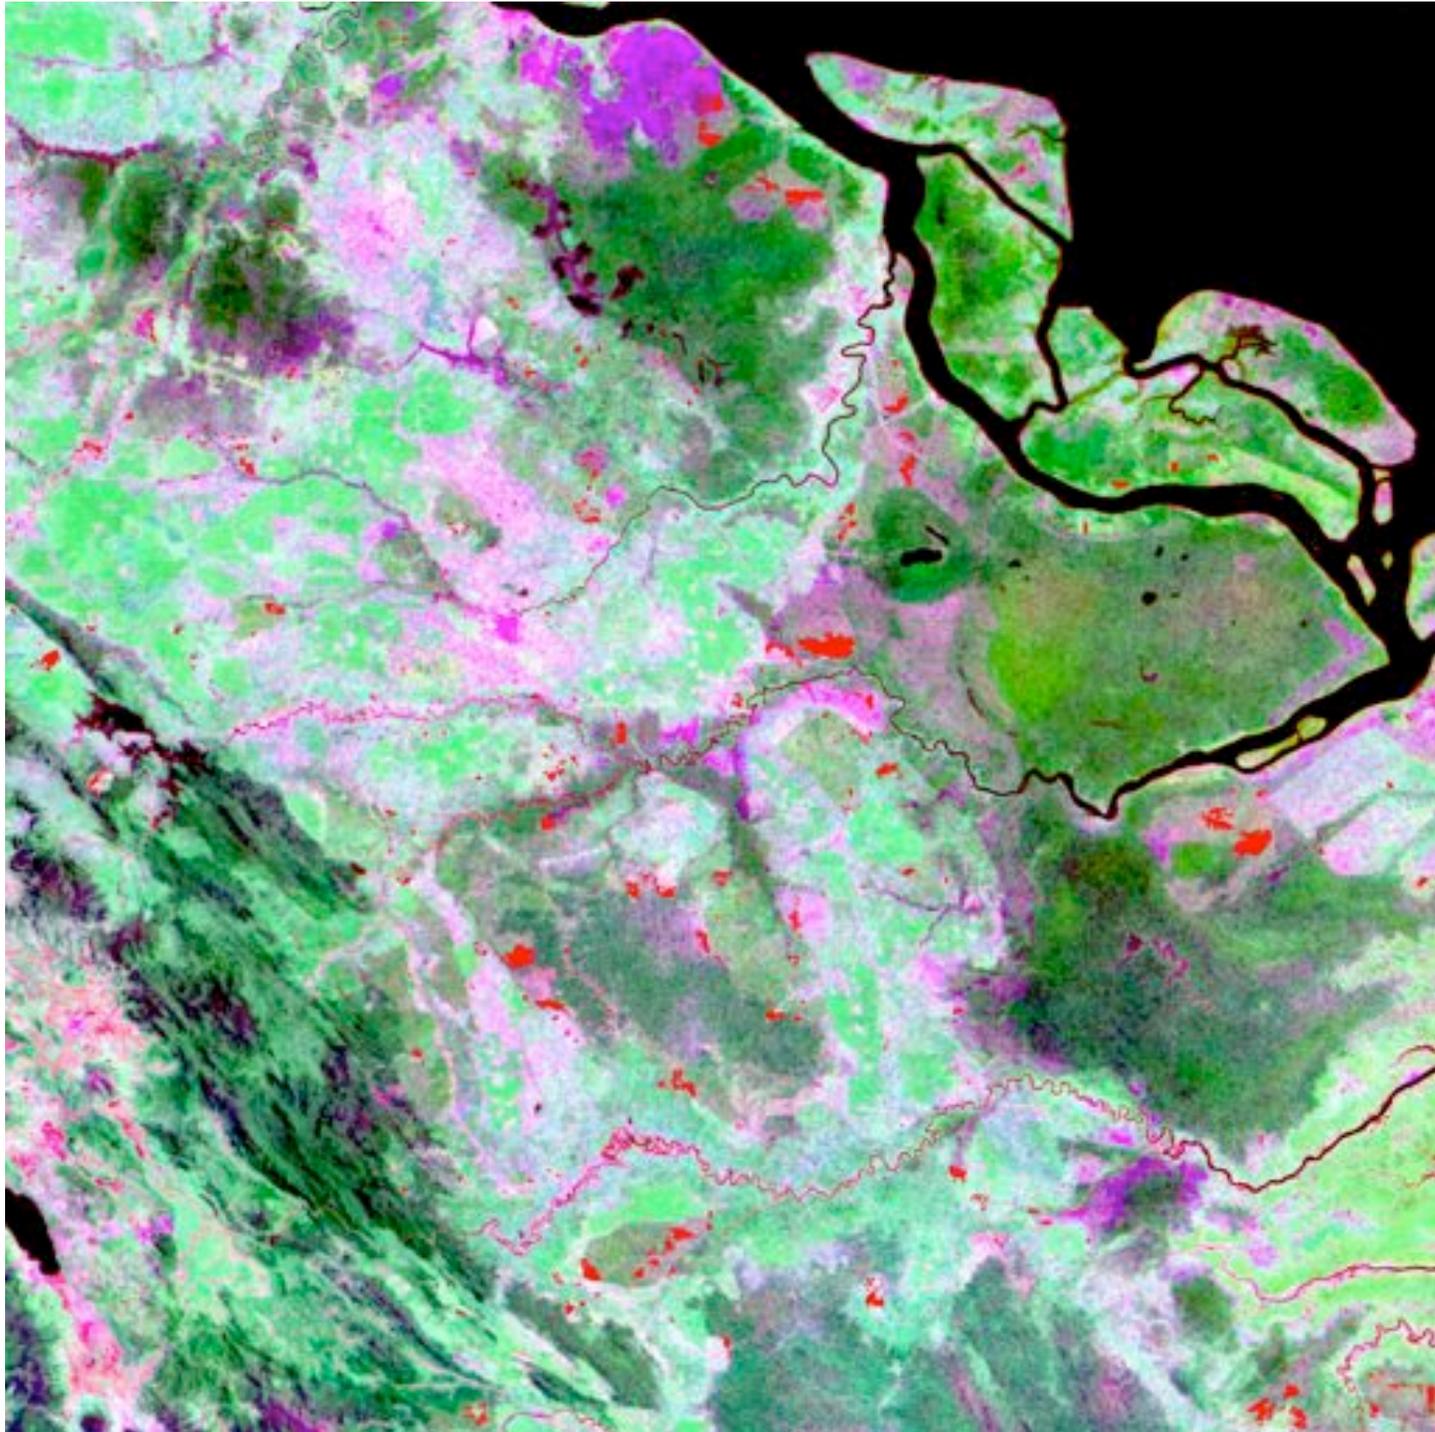

- Employ MODIS to indicate change and develop a stratified sampling frame (low/medium/high) for Landsat-scale analysis
- Acquire and interpret Landsat image pairs per stratum
- Use MODIS change and Landsat change in regression estimator approach to derive final change estimate
- Targeted sampling allows some spatial disaggregation of change

# Forest monitoring using MODIS and Landsat data sets – 2<sup>nd</sup> approach

- Use MODIS to radiometrically normalize Landsat imagery for exhaustive mapping at 30m spatial resolution via:
  - 1) Landsat epochal composites
    - Combine best observations over a given interval to create cloud-free image
    - Cloud-free composites require such a long compositing period that change occurs within the composite interval
  - 2) Landsat time-series characterizations
    - Map each good pixel and create time-series of forest cover estimates in metric space
    - No image composite needed
    - Unequal numbers of cover estimates over the regions (scene overlaps, SLC-off gaps)

# The Democratic Republic of Congo from space - Forest cover loss from 2000 to 2010

All images from the USGS EROS archive for the Landsat Enhanced Thematic Mapper Plus sensor with cloud cover less than 50% were automatically processed and characterized to quantify forest cover loss. The image composite was made from cloud-free observations from 2005 to 2010 and is displayed with a 5-4-3 spectral band combination. Areas in red and orange represent forest cover loss between 2000 and 2010, where red is clearing of mature humid tropical forest and orange is clearing of woodlands and secondary regrowth. Results illustrate the spatial distribution of forest cover loss, with a continued pattern of agricultural clearing, mining, hunting camps and plantation activity.

Application of the Landsat processing and characterization was performed by the Observatoire Satellital des Forêts d'Afrique Centrale (OSFAC), South Dakota State University, and the University of Maryland, and supported by the United States Agency for International Development's Central Africa Regional Program for the Environment (CARPE). Additional support was provided by the United States National Aeronautics and Space Administration and the United States Geological Survey.

MODIS forest  
cover gain (00-08)

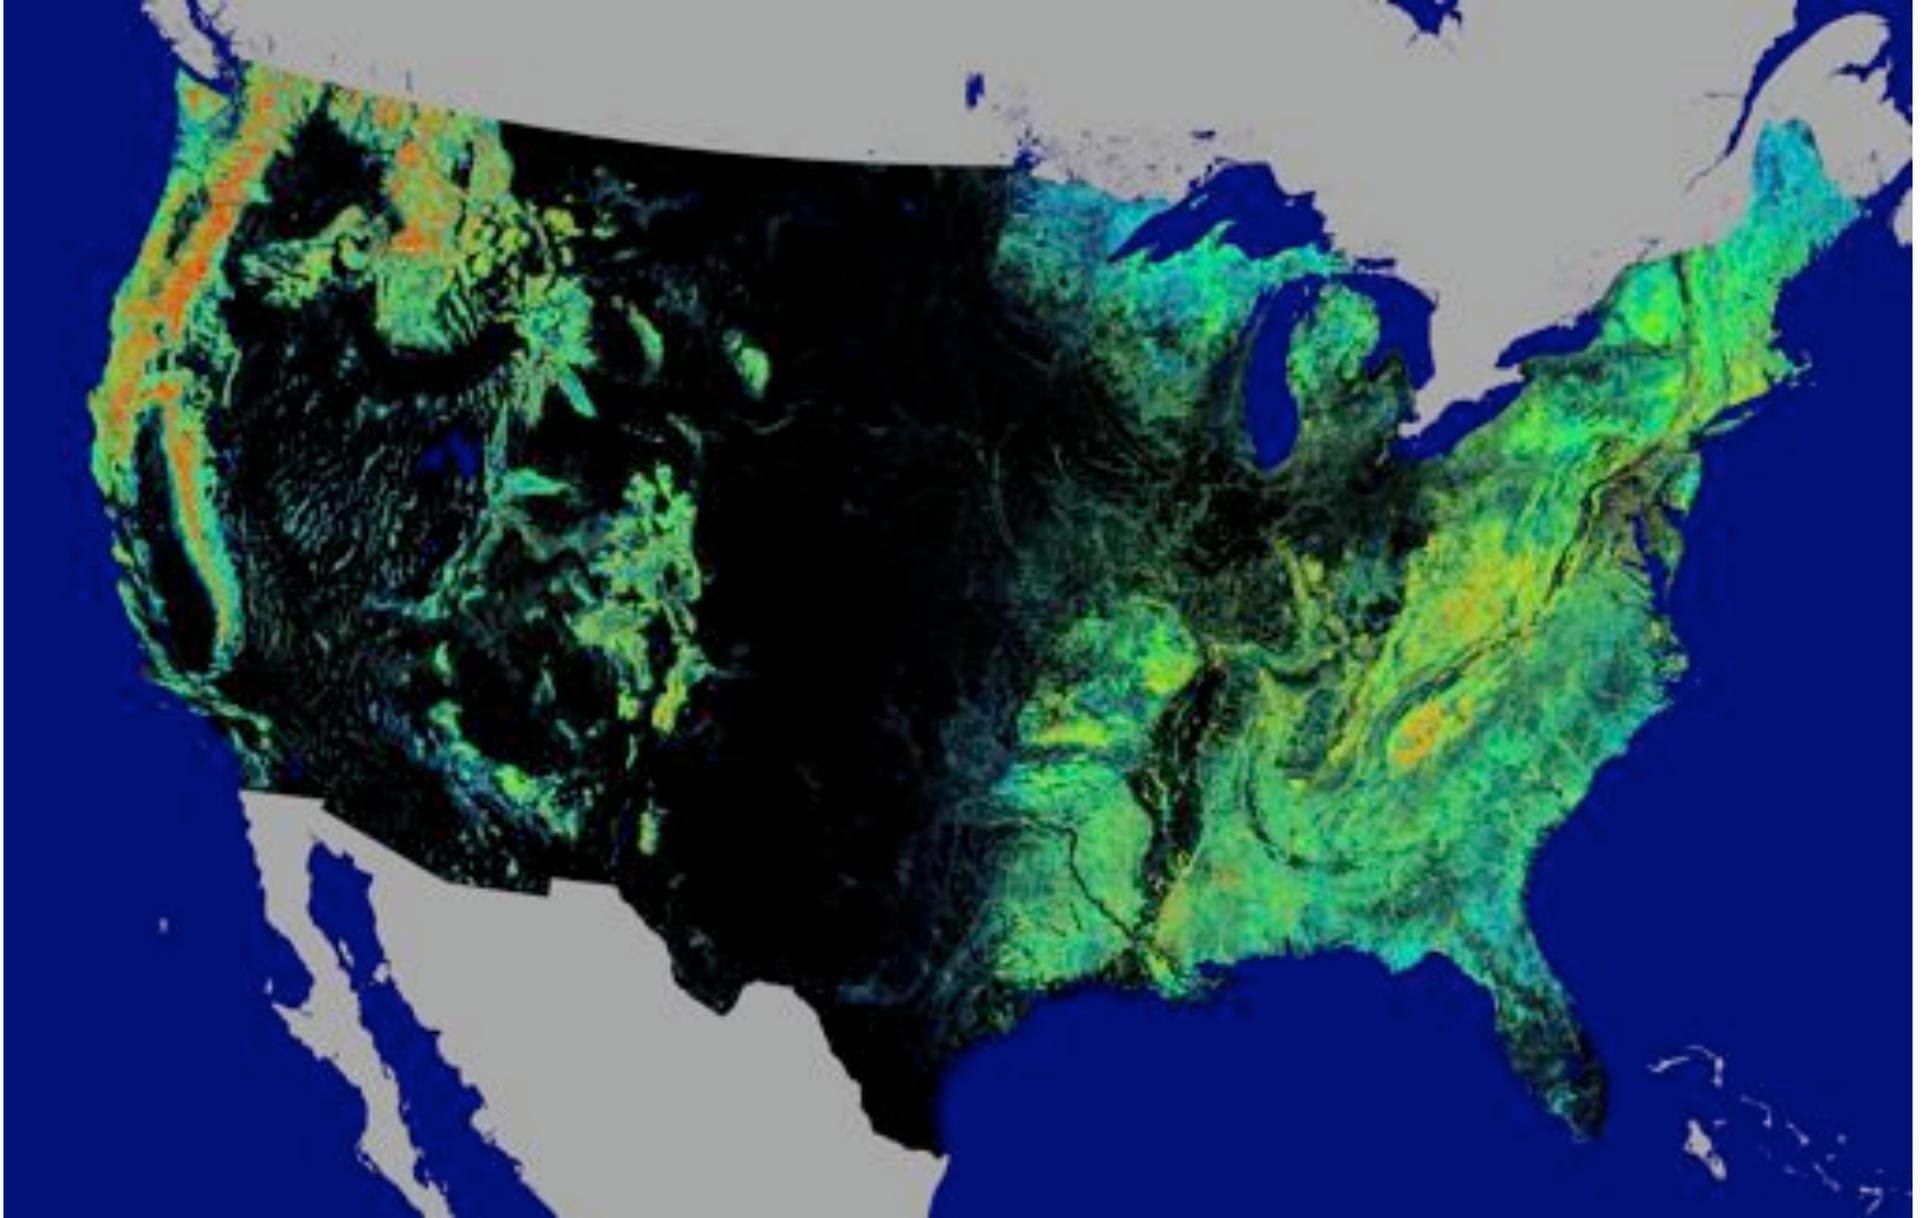

Subsets, 60km x 60km, of change products from Sumatra, Indonesia.

Locations (a-f) of these areas are shown in Figure 5 a). Column one is an r-g-b of three year median vegetation height estimates where bright is tall vegetation and dark is short vegetation; column two is our existing Landsat forest clearing estimate in red for 2000 to 2008 (not calibrated using GLAS); columns three and four are MODIS annual forest cover loss and gain, respectively. For forest cover loss, ■ = 00-01, ■ = 01-02, ■ = 02-03, ■ = 03-04, ■ = 04-05, ■ = 05-06, ■ = 06-07, ■ = 07-08. For forest cover gain, ■ = 00-01, ■ = 01-02, ■ = 02-03, ■ = 03-04, ■ = 04-05, ■ = 05-06, ■ = 06-07, ■ = 07-08.

- Mean HOME for forest-labeled pixels (Landsat)
- Mean HOME for non-forest-labeled pixels (Landsat)
- Time-series HOME estimates for sample locations

# Tree cover height

Red > 25m, green 10-25m, blue 5-10m, black < 5m

# Data requirements for global land cover monitoring

- Systematic global acquisitions
- No/low cost
- Easy access
- Minimal pre-processing required

# Factors affecting Landsat processing that differ from heritage MODIS methods

- Acquisition strategy
- Observation frequency (scene overlap/SLC-off)
- Observation quality (clouds/haze/shadow)
- Phenology

# Characterizing land cover with MODIS and Landsat

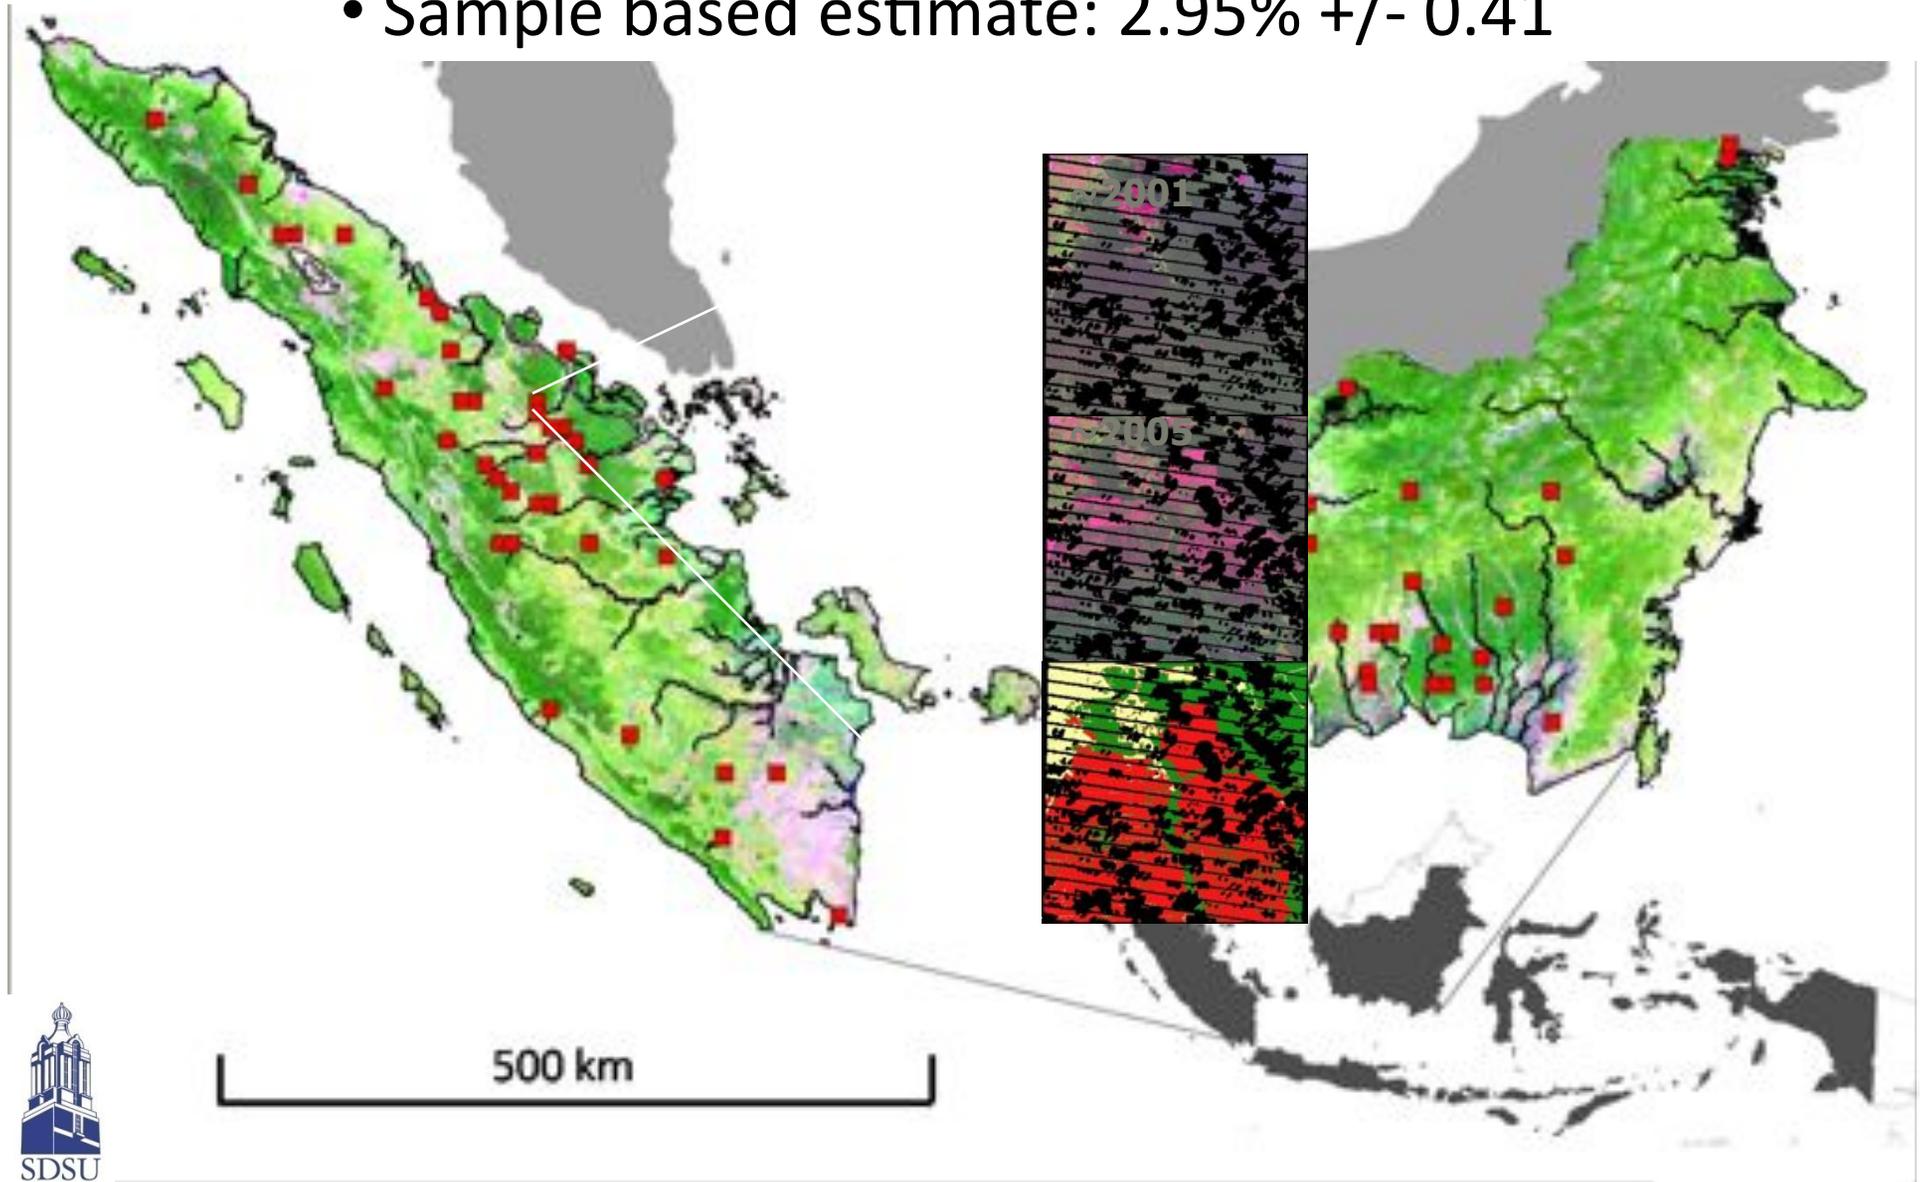

- Methods for generic and automated land cover change monitoring for large areas using Landsat and MODIS are quickly maturing
- Landsat's infrequent and inconsistent acquisition rate makes annual updates of land cover difficult for many parts of the world
- More robust validation protocols and investments are needed, as data products will proliferate with new capabilities
- For developing countries needing to monitor forest cover, the open archive is a boon
  - However, high-performance computing is needed as single image-based methods will not work for many regions
  - How is capacity developed in this context?
