Summary of Modifications for C6 Ice Cloud Models
Bryan Baum, Ping Yang, Andy Heymsfield

Microphysical data:
- more field campaigns (ARM, TRMM, SCOUT, ACTIVE, pre-AVE, midCiX, CRYSTAL-FACE)
- mitigation of contribution from shattered ice particles
- data are being provided by new probes; new insight regarding small particles
- now have ~13,000 individual PSDs, previously had about 1,100
- IWC now ranges from 1.E-6 to 1 g m^{-3} (lower limit previously 1.E-3 g m^{-3})
- development of new habit distribution

Ice particle single scattering libraries now include:
- new habits, e.g., hollow bullet rosette and aggregate of plates
- both roughened and smooth particles
- full phase matrix
- increased resolution in particle size
- host of improvements to light scattering calculations
- updated ice index of refraction (Warren and Brandt, JGR, 2008)
- models will include same properties as before except for delta-transmission energy

New database of single-scattering properties is under development that will cover spectrum from UV through Far-IR with no spectral gaps

A preliminary database provides what is needed for MODIS Collection 6

Use of models with particle roughening will result in lower t and higher D_{eff}
### Expanded Set of Microphysical Data Available

**IWC range: 1.0E-6 to 1 g m\(^{-3}\)**

Number of particle size distributions for each field campaign. The total sample set has been filtered by the requirement that the cloud temperature be colder than \(-40^\circ C\), leading to a total of 12,815 PSDs.
Photomicrograph of snow particles falling at the South Pole Station, 18 August, 1992, at ambient temperature -54°C. The scale bar is 1 mm. Photograph by Stephen Warren.

Images of aggregates of plates provided by A. Heymsfield and C. Schmitt (NCAR). Also shown is a realization of an aggregate of plates used for calculating single scattering properties.
Different Realizations for the Aggregate of Plates
Our models will use properties based on an average of 5 different aggregate particles.
Improvements to Light Scattering Models

New treatment of ray-spreading results in the removal of the term relating to delta-transmission energy at the forward scattering angle.

Improved the mapping algorithm: the single-scattering properties from the new algorithm smoothly transition to those from the conventional geometric optics method at large size parameters.

Semi-analytical method developed to improve the accuracy of the first-order scattering (diffraction and external reflection).

Semi-empirical method is developed to incorporate the edge effect on the extinction efficiency and the above/below-edge effects on the absorption efficiency.
Better transition of extinction/absorption efficiencies between IGOM and ADDA models
